# Advanced Econometrics: Home Assignment 2

Suggested solution for problematic parts and comments

2023

#### Problem 1: GMM

• The moment conditions were not derived correctly in some cases. The correct moment conditions are:

$$E[Y_t] = \mu$$

$$E[Y_t^2] = \mu^2 + \sigma^2 (1 + \theta_1^2 + \theta_2^2)$$

$$E[Y_t Y_{t-1}] = \mu^2 + \sigma^2 (\theta_1 + \theta_1 \theta_2)$$

$$E[Y_t Y_{t-2}] = \mu^2 + \sigma^2 \theta_2$$

$$E[Y_t Y_{t-3}] = \mu^2$$

• For the estimation we need to use the data in the following form:

```
\begin{array}{lll} estimation\_data \, = \, cbind (\, data \, [\, 4\, : \, n \,] \,\, , \\ & data \, [\, 4\, : \, n \,] \,\, \hat{} \, 2 \,\, , \\ & data \, [\, 4\, : \, n \,] \,\, * \,\, data \, [\, 3\, : \, (\, n\, -\, 1\, ) \,] \,\, , \\ & data \, [\, 4\, : \, n \,] \,\, * \,\, data \, [\, 2\, : \, (\, n\, -\, 2\, ) \,] \,\, , \\ & data \, [\, 4\, : \, n \,] \,\, * \,\, data \, [\, 1\, : \, (\, n\, -\, 3\, ) \,] ) \end{array}
```

• Many solutions did not include the interpretation of coefficient significance. The estimates were all significant except for the  $\mu$ .

### Problem 2: Delta method

• The gradient has the following form:

$$\begin{bmatrix} \frac{1}{\beta_0 + \beta_1^2} \\ \frac{2\beta_1}{\beta_0 + \beta_1^2} - \frac{1}{2\sqrt{\beta_1}} \end{bmatrix}$$

• The variance-covariance matrix needs to be adjusted. Since our quantity  $\Phi$  includes only  $\beta_0$  and  $\beta_1$  we need to remove the third column and the third row.

$$vcov[-3, -3]$$

• In the estimation you need to specify the correct expression. The expression does not correspond to our model's  $x_1$  and  $x_2$ , it is only a notation. If you are not sure, it always helps to read the documentation in r. Also, the correct coefficients need to be used. Since  $\Phi$  includes  $\beta_0$  and  $\beta_1$ , only the first two coefficients are used.

$$\begin{array}{c} \operatorname{deltamethod}( \ \ \tilde{} \ \log \left( \operatorname{x1} \ + \ \operatorname{x2^2} \right) - \operatorname{sqrt} \left( \operatorname{x2} \right), \\ \operatorname{coef} \left( \operatorname{model} \right) \left[ 1 \colon 2 \right], \\ \operatorname{vcov} \left( \operatorname{model} \right) \left[ -3, \ -3 \right] ) \end{array}$$

• Lastly, you are supposed to fit the model and estimate the variance of  $\Phi$  based on the estimated parameters taken from the model, the true values are there to generate the data.

# Problem 3: Bootstrap

- You were asked to plot the exponential q-q plot. There are many options for how to do that, you can use for example  $\mathbf{qqexp}()$  function, or  $\mathbf{plot}()$  function where you specify the theoretical quantiles of exponential distribution with  $\lambda = 2$ .
- The theoretical variance is  $1/\lambda^2$ .
- In many cases the discussion was missing. Pay attention to the setup and what exactly you are asked.

# Problem 4: Endogeneity

- The model we are trying to estimate does not include variable  $x_2$ . This omitted variable is causing the endogeneity.
- Relevant instrumental variables are:  $z_1$ ,  $z_2$ , and  $z_4$ , But only  $z_1$  is valid, because  $z_2$ , and  $z_4$  are included in the equation defining  $x_2$ .
- Our estimated model does not include  $x_2$ , which would therefore fall into the error term. Thus when checking the correlations with the error term of our model, we need to acknowledge, that  $x_2$  is also a part of it.
- The 2SLS is a consistent estimator of both  $\beta_1$  and  $\beta_3$ . The OLS is a consistent estimator only for  $\beta_3$ .

without $x_2$ .			

ullet  $x_2$  should not be included in the model. We are interested in estimating the model
